

Deployment process to Heroku by initializing Git repository

- We might have multiple developers and each developer might have their local environments (server, terminal)
- Developers push their work and updates to a version control system like GitHub
- So when the developer makes changes, the updates are pushed to github. However, leaving it on github doesn't make it available to the public. So, we need some software to load the changes to the server.
- So that is where the host server comes to play.
- Hence, deployment is basically taking the information or code for Version control system sent through developer's local environment and sending it to the host server to make it available to the public.
-
